Q: Joint probability. I am given the following statement: In a sample of 10,000 patients, 5% of patients over 30 years old, have a disease. What is the probability that a randomly selected patient over 30 years old has the disease? I am asked to solve this problem without any help from anyone else. I used what is called "negative binomial approximation" but I am stuck. Can someone please help me please? Thank you very much in advance!

A: The problem is that it is not specified what is meant by "the probability that a randomly selected patient over 30 years old has the disease". Meaning of "over 30 years old" is that 5% of them have disease. If you draw 5% of patients with blue eyes from a group of patients that have same proportions of patients with blue eyes and patients with other eye colors, then what proportion of blue-eyed patients are you drawing? Or instead of drawing a sub-sample from a group of patients, you take a random sample from the group of patients. That's where the negative binomial approximation comes in. If the sampling of a sub-sample of patients is repeated N times, then the conditional probability (of i successes in the

samples if the probability of a single success is p is

$$\Pr[S=i \mid N=n] = \binom{n}{i} p^i (1-p)^{n-i}$$
 where the binomial coefficient means that the population consists of n patients, out of which i get the disease. Plugging in $p=0.05$, $n=10,000$ and $i=5$, we get

$$\Pr[S=5 \mid N=10,000] = \binom{10,000}{5} 0.05^5 (1-0.05)^{10,000-5} = 0.00012$$
 and thus the probability that a randomly selected patient over 30 years old has the disease is approximately $\frac{1}{1,200}$:
